# Synthetic workplace ergonomics example

This is an original synthetic fixture for software examples, not a research finding.

Neutral posture is defined as a spinal alignment that maintains the natural curves of the spine during seated work. Neutral spine posture is an alternate label for the same position.

Supported posture is a seated position in which external supports reduce the effort of maintaining alignment. The two factors are distinct: a worker may adopt neutral posture with or without a support.

These named posture factors can be recorded as ergonomic labels when observing a workstation.
